COMPANY INFORMATION

Company / Organisation Name
gassProductions

Product Name (optional)
AI-Assisted Multi-Camera Live Production

Questions / Answers

Company profile

gassProductions is a specialist multi-camera production and live streaming company founded in 2006, based in Kent, UK. We deliver vision mixing, camera operation, and live streaming services for corporate events, product launches, conferences, and creative brand activations across the UK and internationally.

Our client roster includes some of the world's most recognised technology and consumer brands — Sony, Adobe, Google, AWS, Microsoft, BMW, and Goldwell among them. We're trusted to deliver technically demanding, high-profile productions where failure isn't an option.

In 2024, gassProductions became one of the first UK production companies to adopt Sony's BRC-AM7 AI PTZ camera system for live event work. Rather than simply deploying new equipment, we developed a complete production methodology around AI-assisted camera operation — separating mechanical tracking from creative decision-making. This approach has become our standard operating model for corporate events.

Our work with the BRC-AM7 led to a direct feedback relationship with Sony's R&D team, contributing to four firmware improvements shipped in the V3.0 update announced at ISE 2026. Sony subsequently commissioned gassProductions to produce the official global case study film documenting our methodology and results.

We're a focused team combining deep technical expertise with creative storytelling.

YOUR PRODUCT

Questions / Answers

Description of your technology

Our innovation is not a product in the traditional sense — it's a production methodology that fundamentally redefines the relationship between AI technology and human creativity in live event production.

The methodology centres on a deliberate separation of two functions that have always been inseparable in multi-camera production: mechanical tracking (the repetitive pan, tilt, and zoom adjustments required to keep moving subjects in frame) and creative decision-making (composition, shot selection, visual storytelling, and editorial judgement).

Using five Sony BRC-AM7 AI PTZ cameras operated by just two crew members, we've demonstrated that AI can handle the mechanical tracking burden — which traditionally consumes approximately 80% of a camera operator's attention — while human operators focus exclusively on the creative dimensions of production that require human judgement, emotional intelligence, and storytelling instinct.

This creates a role that didn't previously exist in live event production: the multi-camera creative director. Instead of one operator managing one camera (performing both mechanical and creative functions), a single operator now creatively directs two or three AI-assisted cameras simultaneously — making compositional decisions, managing shot variety, and directing the visual narrative across multiple viewpoints.

The practical impact is measurable. At Goldwell's Celebration of Color — a high-pressure runway show at Exhibition White City, London — our two-person crew delivered broadcast-grade five-camera coverage that would traditionally require five operators. The AI operated at approximately 90% autonomy during the live show, and the quality was independently verified by Vibration Production, the AV supplier managing the event.

Critically, this methodology is distinct from both automated lecture capture (where cameras operate entirely without human creative input) and traditional PTZ remote operation (where an operator still manually controls each camera's tracking). Our approach occupies a new space between these: AI handles the mechanics, humans handle the creativity, and the result is production quality that exceeds either approach alone.

The methodology proved so compelling that Sony Professional Europe commissioned gassProductions to produce the official global case study film, now distributed worldwide. Our operational feedback also directly influenced four firmware improvements in Sony's V3.0 update announced at ISE 2026, demonstrating that this methodology doesn't just use AI technology — it actively advances it.

The approach is inherently scalable and replicable. Any production company with BRC-AM7 cameras can adopt the same methodology. Our case study provides a documented blueprint, and the firmware improvements we influenced are available to all operators globally. This is now gassProductions' standard operating model for corporate events.

TECHNOLOGY DESCRIPTION

Questions / Answers

Explain how the AI works in your solution?

The Sony BRC-AM7 uses on-device AI powered by Sony's BIONZ XR processor — the same chip found in their flagship cinema and mirrorless cameras. All AI inference runs locally on the camera hardware with zero cloud dependency, zero data transmission, and zero latency.

The AI engine performs real-time skeletal tracking, head detection, face recognition (with priority subject registration), and clothing pattern analysis to maintain consistent framing of moving subjects. It can simultaneously track up to 8 individuals across more than 150 composition presets, automatically adjusting pan, tilt, and zoom to keep subjects framed according to operator-defined parameters.

The camera features a 1.0-inch Exmor RS CMOS sensor with 20x optical zoom (24–480mm equivalent) and up to 40x Clear Image Zoom in Full HD — delivering broadcast-quality imagery that matches or exceeds traditional manned camera positions.

Critically, the AI handles the mechanical burden of tracking — the repetitive pan/tilt/zoom adjustments that traditionally consume approximately 80% of a camera operator's attention. Manual operator override is available at any time, allowing instant human intervention for creative decisions or unexpected scenarios. This is not fully autonomous filming — it's AI-assisted production where the technology handles mechanics and humans retain complete creative control.

What specific problem does this AI solve?

In traditional multi-camera live production, every camera operator performs two fundamentally different tasks simultaneously: mechanical tracking (keeping subjects framed through constant pan, tilt, and zoom adjustments) and creative decision-making (composition, shot selection, storytelling). These tasks require different skills — one is repetitive and reactive, the other is creative and intentional — but they've always been coupled in a single role.

This coupling creates three problems. First, it's expensive: five cameras means five operators, making broadcast-quality multi-camera production economically inaccessible for most events. Second, it's limiting: because operators spend approximately 80% of their attention on mechanical tracking, only 20% goes toward creative decisions — limiting the creative potential of multi-camera production. Third, it's space-intensive: five manned camera positions require dedicated floor space.

Our methodology solves all three problems by deliberately decoupling these functions. AI handles the mechanical tracking entirely, freeing operators to focus 100% of their creative attention across multiple cameras. The result is 60% fewer crew, reduced physical footprint, and more creative, more dynamic coverage because operators are no longer cognitively overloaded with mechanical tasks.

This makes broadcast production accessible to events that previously couldn't afford it, while simultaneously improving creative quality.

Questions / Answers

What makes your approach different or innovative?
We created the multi-camera creative director role — one operator managing two or three AI cameras while AI handles mechanical tracking.

This is architecturally different from existing models. Automated lecture capture removes human creativity. Traditional PTZ operation requires manual control. Surveillance automation prioritises coverage over composition. Our approach has AI handling mechanics at ~90% autonomy, human operators spending 100% creative attention across multiple cameras.

What traditionally required five operators is now delivered by two, managing creative output across five cameras. This isn't cheaper coverage — it's more creative coverage. Operators freed from mechanical tracking deliver more dynamic shot variety and intentional visual storytelling.

Our methodology advanced the technology. Four Sony firmware improvements trace to our feedback. Sony commissioned our case study film as the global reference implementation. At ISE 2026, our methodology was showcased alongside the V3.0 announcement, connecting production methodology to technology advancement. We reshaped how the technology is understood and deployed industry-wide.

VALIDATION

Questions / Answers

How did you test, validate, or quality-check the AI outputs to ensure they were accurate, safe, or reliable?
We needed to prove that operators freed from mechanical tracking would actually deliver more creative, more dynamic coverage — not just cheaper coverage.

Goldwell's Celebration of Color provided this proof. This flagship runway show combined every challenge that stress-tests both the AI technology and the creative methodology: fast-moving performers on a catwalk, dramatic and constantly shifting lighting (critical for a hair colour brand), 180-degree directional changes, multiple performers in close proximity, fast-paced timing with zero tolerance for missed shots, and an audience of industry professionals expecting broadcast-quality results.

Critically, this was not a controlled demonstration. Vibration Production, an established AV company, engaged gassProductions specifically for our methodology on a real commercial event. Failure would be visible and consequential.

The validation required answering a specific question: when operators are freed from mechanical tracking, do they actually deliver superior creative coverage? The answer came through detailed analysis of the five-camera live production.

During the show, the AI operated at approximately 90% autonomy — handling sustained tracking during long walks, rapid directional changes, lighting transitions, and close-proximity crossovers without requiring corrective intervention. Our two operators managed all five cameras' creative output. We documented shot composition choices, shot duration, transitions between cameras, and the pacing of the vision mix.

Analysis confirmed the hypothesis. The shot variety was measurably higher than typical five-operator deployments — more compositional diversity, more intentional use of different focal lengths, more dynamic transitions between cameras. The vision mixing demonstrated greater sensitivity to the creative moment (cutting to tight shots during emotional moments, holding wide shots for dramatic entrances) rather than following mechanical patterns. The overall visual narrative showed more purposeful editorial choice and storytelling instinct.

This difference was independently validated by Spierin: "They setup with a fraction of the footprint and crew we'd normally expect — without compromising broadcast quality." But the quality wasn't just maintained — it was elevated. The creative sophistication of the output exceeded what they'd typically commission.

Spierin's second statement provided methodology validation: "They don't just turn up with cameras — they arrive with solutions. That's why we trust them on technically demanding live shows." This confirmed the value proposition extends beyond efficiency to creative capability.

Sony Professional Europe's decision to commission our global case study film represented validation at the manufacturer level. Sony chose our methodology — specifically our approach to human-AI creative collaboration — as the reference implementation for their AI camera technology worldwide.

The case study was showcased at ISE 2026 alongside the V3.0 firmware announcement. Presenting our creative methodology on the industry's largest stage provided industry-level validation of our approach.

Post-event technical analysis documented not just AI tracking accuracy but creative output metrics: shot composition variety, framing diversity, vision mixing responsiveness. This data demonstrated that separating mechanical tracking from creative decision-making doesn't just reduce crew — it elevates creative quality.

Questions / Answers

Subsequent event deployments confirmed repeatability. The creative output quality we achieved at Goldwell has been consistently reproduced across different events, venues, and performer types.

IMPACT

In one summary, explain the overall impact of your AI solution. Please cover four areas: innovation, execution, user or customer outcomes, and measurable results.

Questions / Answers

Innovation

The core innovation is a paradigm shift in what camera operators actually do during live production.

For decades, the camera operator's role has been defined by a fundamental constraint: one person manages one camera, spending approximately 80% of their cognitive effort on the mechanical task of tracking — constantly adjusting pan, tilt, and zoom to keep subjects framed. Only the remaining 20% goes toward creative decisions about composition, shot selection, and visual storytelling.

Our methodology inverts this ratio. By offloading mechanical tracking entirely to AI, operators now spend approximately 90% of their attention on creative decisions — and they do this across multiple cameras simultaneously. This isn't incremental improvement; it's a fundamental redefinition of what the role involves.

The result is a new production paradigm: the multi-camera creative director. One operator creatively manages two or three AI-assisted cameras, making real-time decisions about composition, shot variety, and visual narrative across multiple viewpoints. They're not monitoring whether the AI is tracking correctly (it operates at ~90% autonomy) — they're actively shaping the creative output of the entire multi-camera production.

This is architecturally different from every existing approach to camera automation. Automated lecture capture removes human creativity entirely — cameras follow rules, not creative intent. Traditional PTZ remote operation still couples mechanical control with the operator — they're just doing it from further away. Surveillance-style automation prioritises coverage over composition. Our methodology preserves and amplifies human creativity while eliminating the mechanical constraint that has limited it.

The innovation also extends to making broadcast production economically accessible. A five-camera shoot that traditionally requires five operators (plus rigging, plus space) can now be delivered by two people with compact PTZ positions. Events that previously couldn't justify broadcast-quality multi-camera coverage — mid-tier corporate conferences, brand activations, awards ceremonies — can now access it at a fundamentally different cost point. We're not just doing the same thing cheaper; we're enabling a quality level that was previously unavailable to this market segment.

At a technology level, our methodology generated real-world operational data that no laboratory testing could replicate. Live events present unpredictable variables — performers deviating from expected paths, lighting changes, rapid timing shifts — that expose AI limitations requiring platform refinement.

Our structured feedback to Sony resulted in four specific V3.0 firmware improvements: optical image stabilisation for long-lens AI tracking, Tracking Range Zone overlays for 9:16 output monitoring, PTZ Speed Adjustment during active auto-framing, and improved control interface visibility. These improvements benefit every BRC-AM7 operator worldwide, meaning our methodology's innovation extends well beyond our own productions.

The combination of creating a new creative paradigm, making broadcast production accessible to a wider market, and actively driving technology improvement through real-world feedback represents multi-layered innovation. We didn't just find a clever use for AI cameras — we rethought the fundamental relationship between human creativity and AI capability in live production, and then fed those insights back to the manufacturer to advance the platform for everyone.

Questions / Answers

Execution

The methodology was executed at Goldwell's Celebration of Color — a flagship runway show at Exhibition White City, London — where gassProductions was engaged by Vibration Production for AI camera expertise.

Pre-production included venue assessments to determine optimal camera positions for AI tracking, considering sightlines, lighting, and performer movement patterns. Each Sony BRC-AM7 camera was assigned a specific field of view with AI tracking parameters configured for its role. Priority subject registration ensured the AI maintained preferential framing on featured performers. AI tracking sensitivity was tuned to respond appropriately to runway speeds without over-correcting.

On the day, deployment was remarkably compact. Five PTZ cameras replaced five traditional manned positions, directly increasing audience seating capacity.

The two-person crew — Dan Radford and one additional operator — managed all five camera feeds via Blackmagic ATEM vision mixing, real-time shading, and ISO recording.

During the live show, the AI handled tracking autonomously at approximately 90%. Performers were tracked through the complete runway sequence: entrance, sustained walk under changing lighting, turn at the far end, return, and exit. The system maintained framing through 180-degree turns and dramatic lighting transitions.

The creative workflow was highly dynamic. Camera selection varied continuously — holding wide shots to establish context, cutting to tight shots for detail work. When performers crossed paths, operators made real-time decisions about featured cameras, anticipating narrative moments. Vision mix pacing reflected editorial choices: holding shots for impact, cutting on movement, matching music and energy.

Real-time creative decisions included: holding the side camera during emotional pauses, cutting to faces during styling reveals when wide shots showed less detail, timing cuts to audio cues, managing coverage across simultaneous model changes. These decisions required creative intention — exactly what was freed by removing mechanical tracking burden.

Camera shading was managed simultaneously — adjusting iris, colour balance, and exposure across all five feeds to maintain colour consistency under dramatic lighting. Our two crew members integrated this seamlessly because they weren't cognitively overloaded with mechanical tracking.

Post-event, gassProductions produced the official Sony case study film commissioned by Sony Professional Europe. This involved behind-the-scenes footage, interviews, and a documentary-style piece demonstrating the methodology for Sony's global professional audience.

Technical reviews documented AI tracking performance across different scenarios: lighting conditions, subject speeds, directional changes, and edge cases. These reviews were structured into specific feedback for Sony's R&D team, directly informing the four V3.0 firmware improvements announced at ISE 2026.

The case study film was showcased at ISE 2026 alongside the firmware announcement, connecting execution directly to the technology advances it inspired.

Questions / Answers

Outcome

Operators freed from mechanical tracking deliver measurably more creative coverage — and this methodology is now gassProductions' standard for every corporate event.

The methodology's outcomes demonstrate impact across four distinct levels: individual production, operational model, technology advancement, and industry influence.

At the individual production level, Goldwell's Celebration of Color was a clear success. Two operators delivered broadcast-grade five-camera coverage of a demanding runway show with zero production failures. The client received coverage meeting or exceeding what a traditional five-operator setup would deliver, at significantly lower crew cost with a much smaller physical footprint.

At the operational model level, the methodology's success has led to its adoption as gassProductions' standard approach for corporate events. Every multi-camera production we deliver uses this AI-assisted methodology, consistently reproducing the efficiency gains and quality standards demonstrated at Goldwell. This proves the methodology is commercially viable, repeatable across different event types, and sustainable.

The transition created a new value proposition for our clients. Events that previously fell below the economic threshold for broadcast-quality production can now access it. A three or five-camera setup operated by two crew members costs significantly less than traditional equivalents while delivering comparable or superior creative output — because operators freed from mechanical tracking are more creative.

At the technology advancement level, our methodology directly shaped the next generation of tools. The four V3.0 firmware improvements — optical image stabilisation for long-lens tracking, Tracking Range Zone overlays, PTZ Speed Adjustment during auto-framing, and improved control visibility — were specific solutions to specific problems encountered during real productions. This demonstrates production methodology can drive technology development, creating a virtuous cycle between users and manufacturers.

Sony's decision to commission our case study film validates this outcome. The manufacturer chose a small, specialist UK production company as the global reference implementation for their AI camera technology. This reflects the methodology's strength.

At the industry influence level, the global case study film and ISE 2026 showcase have made our methodology visible to production professionals worldwide. The film provides a documented, replicable approach any production company can adopt.

Dan Radford's positioning — "The AI tracking doesn't replace us — it empowers us to be more creative" — has contributed to a more constructive industry conversation about AI's role in events. Rather than technology versus people, the framing is technology amplifying people. This matters because the industry's AI relationship is still forming, and current narratives will influence adoption patterns for years.

Vibration Production's Niall Spierin summarised the outcome: "They don't just turn up with cameras — they arrive with solutions." This captures exactly what the methodology achieves: transforming AI cameras from equipment into solutions delivering measurably better creative results with measurably fewer resources.

Questions / Answers

Results

The measurable results from our AI-assisted creative production methodology span efficiency, quality, technology impact, and industry reach.

Crew efficiency: A 60% reduction in camera crew — two operators replaced five — with no compromise in broadcast quality. This was maintained throughout the live Goldwell's Celebration of Color runway show, not just in ideal conditions. Both operators simultaneously managed vision mixing, camera shading, ISO recording, and creative direction of all five camera feeds.

Creative output transformation: Operators shifted from spending approximately 80% of attention on mechanical tracking to spending approximately 90% on creative decisions — composition, shot variety, visual storytelling, and vision mixing. This measurably changes the nature of the production output, not just its cost structure. Coverage is more dynamic and creatively intentional because operators are freed to think about storytelling rather than wrestling with mechanical controls.

AI autonomy: Approximately 90% autonomous operation during a live, high-pressure, zero-retake runway show. The AI successfully tracked performers through sustained runway walks, 180-degree directional changes, dramatic lighting transitions, and close-proximity crossovers. The approximately 10% human intervention was predominantly creative rather than corrective.

Physical footprint: Compact PTZ camera positions eliminated manned camera platforms, directly increasing audience seating capacity and providing additional floor space for wider event production needs. This is a tangible commercial benefit for venues and event organisers.

Quality verification: Broadcast quality independently confirmed by Vibration Production — an experienced AV supplier who regularly commissions traditional camera crews. Director Niall Spierin: "They setup with a fraction of the footprint and crew we'd normally expect — without compromising broadcast quality."

Firmware influence: Four specific Sony BRC-AM7 V3.0 firmware improvements directly traceable to our operational feedback — optical image stabilisation for long-lens AI tracking, Tracking Range Zone overlays for 9:16 output monitoring, PTZ Speed Adjustment during auto-framing, and improved control interface visibility. Announced at ISE 2026, these improvements benefit all BRC-AM7 operators globally.

Sony case study: Official global case study film commissioned by Sony Professional Europe, produced by gassProductions, distributed through Sony's worldwide professional channels. This represents manufacturer-level validation of our methodology.

ISE 2026: Case study showcased at the world's largest professional AV trade show alongside the V3.0 firmware announcement — positioning our methodology on the industry's most prominent global stage.

Dan Radford quoted on Sony's platform: "The AI tracking doesn't replace us — it empowers us to be more creative" — a statement that has influenced how AI adoption is discussed across the events industry.

Second statement from Niall Spierin: "They don't just turn up with cameras — they arrive with solutions. That's why we trust them on technically demanding live shows" — validating the methodology's value beyond simple equipment deployment.

Questions / Answers

Methodology adoption: Now gassProductions' standard operating model for corporate events, confirming sustainable, repeatable results across different event types and venues.

Market accessibility: Broadcast-quality multi-camera production now economically accessible to events that previously couldn't justify the crew costs — expanding both our addressable market and production quality standards across the industry.

CASE STUDY

Questions / Answers

Describe how the AI was used in practice.
The case study is Goldwell's Celebration of Color — a flagship runway show at Exhibition White City, London, produced by Vibration Production with gassProductions engaged specifically for AI camera expertise.

This event was selected because it represents one of the most challenging environments for AI-assisted camera operation. A runway show combines sustained, directional movement with sudden changes — performers walk steadily along a catwalk, then execute a 180-degree turn, often under dramatically different lighting. For a hair colour brand, accurate colour reproduction under varying lighting is brand-critical. Multiple performers may be on the runway simultaneously, creating tracking priority decisions. The pace leaves zero margin for missed shots.

Vibration Production engaged gassProductions specifically for our AI camera methodology. This was a genuine commercial engagement — not a demonstration we arranged. Vibration needed broadcast-quality multi-camera coverage with minimal crew and compact footprint, and chose our AI-assisted approach.

We deployed five Sony BRC-AM7 AI PTZ cameras with two operators. Camera positions were strategically planned for optimal AI tracking: clear sightlines along the full runway, appropriate distances for the 20x zoom range, and positions enabling AI to track through walk-turn-return sequences.

AI tracking parameters were configured for each camera's role. Wider establishing shots had different framing parameters than tighter feature cameras. Priority subject registration was set for featured performers in each collection segment. Tracking speed parameters adjusted based on expected movement pace.

During the live show, the methodology was tested under demanding conditions. The AI tracked performers through:
— Sustained forward movement along the full runway
— 180-degree turns at the runway end (challenging tracking involving rapid directional change)
— Transitions between dramatically different lighting environments
— Close-proximity moments where multiple performers were within the same camera's field
— Varying performer speeds

Our two operators managed all creative decisions across five cameras: which shot was live, composition adjustments, shot variety, visual pacing, camera shading for colour consistency, and vision mixing. The AI handled approximately 90% of tracking autonomously.

Post-event, Vibration Production's Director Niall Spierin provided two statements anchoring our case study: "They setup with a fraction of the footprint and crew we'd normally expect — without compromising broadcast quality" and "They don't just turn up with cameras — they arrive with solutions."

Sony Professional Europe reviewed the production and commissioned gassProductions to produce the official global case study film — featuring behind-the-scenes footage, methodology explanation, and interviews. This film is distributed through Sony Professional's worldwide channels and was showcased at ISE 2026.

Questions / Answers

What measurable results or improvements did it deliver?
(Include any evidence that shows real-world impact.)

The Goldwell's Celebration of Color case study delivered the following measurable results.

Crew reduction: Two operators delivered complete broadcast-grade five-camera coverage — a 60% reduction from the traditional five-operator model. Both operators managed vision mixing, real-time camera shading, ISO recording, and creative direction simultaneously. The crew reduction fundamentally changed the nature of the work: operators shifted from mechanical tracking to creative direction of multiple AI-assisted cameras.

AI autonomy: Approximately 90% autonomous tracking during the live runway show. The AI successfully maintained framing through sustained performer walks, 180-degree directional changes, dramatic lighting transitions (from warm spotlight to cool wash — critical for a hair colour brand), and close-proximity moments with multiple performers. Human intervention was approximately 10%, predominantly creative in nature.

Creative quality: Independent assessment from Vibration Production confirmed that broadcast quality was maintained. Their Director, Niall Spierin, compared our two-person AI setup directly against traditional five-operator deployments — and found no quality compromise. This external validation from an experienced industry professional provides meaningful verification.

Physical footprint: Five compact PTZ camera positions replaced five manned camera setups. This directly increased audience seating capacity and freed floor space for Vibration Production's wider event requirements. Manned camera positions typically require a tripod, operator, and surrounding access space — eliminating all five of these installations created meaningful space savings.

Colour accuracy: Camera shading was maintained across all five feeds throughout the show, ensuring consistent colour reproduction. For Goldwell — a hair colour brand — this is a critical quality metric that we managed in real-time with just two operators.

Sony case study commission: Sony Professional Europe commissioned gassProductions to produce the official global case study film — selecting our methodology as the flagship demonstration of BRC-AM7 AI capabilities worldwide. The film is distributed through Sony Professional's global channels, reaching production professionals, integrators, and event organisers internationally.

Firmware improvements: Four BRC-AM7 V3.0 firmware improvements are directly traceable to our operational feedback from this case study event: optical image stabilisation for long-lens AI tracking (we identified vibration issues during telephoto shots), Tracking Range Zone overlays (we needed framing boundary visualisation for 9:16 vertical outputs), PTZ Speed Adjustment during auto-framing (we needed creative control over movement speed), and improved control interface visibility (we identified monitoring challenges in bright venue environments).

ISE 2026 showcase: The case study was presented at the world's largest professional AV trade show, alongside the V3.0 firmware announcement. This connected our production methodology directly to the technology improvements it influenced, on the industry's most prominent global stage.

Client testimonials: Niall Spierin (Vibration Production): "They setup with a fraction of the footprint and crew we'd normally expect — without compromising broadcast quality" and "They don't just turn up with cameras — they arrive

Questions / Answers

with solutions." Dan Radford on Sony's platform: "The AI tracking doesn't replace us — it empowers us to be more creative."

Methodology adoption: The AI-assisted production model has been adopted as gassProductions' standard approach for corporate events, confirming the case study results are repeatable, reliable, and commercially sustainable.

MODEL TRANSPARENCY (optional)

What type of AI model or technique does your solution use? Please provide a simple, high-level explanation that helps judges understand the approach (no confidential or proprietary details required).
The AI system used in our production methodology is entirely contained within the Sony BRC-AM7 PTZ camera hardware. There is no external AI platform, cloud processing, or third-party machine learning service involved.

The core AI engine runs on Sony's BIONZ XR processor — the same chip used in Sony's flagship Alpha mirrorless cameras. This processor handles all inference tasks locally, ensuring zero-latency response and zero data transmission to external servers.

The AI capabilities include four primary functions. First, skeletal tracking: the system identifies and follows human body structure, maintaining framing even when subjects turn away or are temporarily occluded. Second, head detection: a complementary tracking method for tightly packed groups or loose-fitting clothing. Third, face recognition with priority subject registration: operators can register individuals as priority subjects, ensuring preferential framing on key speakers, performers, or VIPs. Fourth, clothing pattern analysis: the system identifies subjects by distinct patterns, particularly useful in fashion events where multiple subjects have similar characteristics.

The camera can simultaneously track up to 8 subjects and offers more than 150 composition presets, giving operators granular control over AI framing. These presets define parameters such as headroom, lead room, subject size, and camera response speed.

Hardware specifications relevant to AI performance include: a 1.0-inch Exmor RS CMOS sensor (delivering superior image quality in challenging lighting), 20x optical zoom, up to 40x Clear Image Zoom in Full HD, and 4K/60p recording with simultaneous streaming capability.

Regarding data privacy: because all AI processing happens on-device, no personal data ever leaves the camera hardware. There is no cloud upload, no external data storage, and no transmission mechanism. When powered off, all tracking data is discarded. This makes the system GDPR-compliant for live events, as no personal data is processed beyond real-time, in-camera inference.

The AI operates as an assistive tool, not an autonomous system. At any point, a human operator can override the AI's decisions — adjusting framing, switching subjects, or taking full manual control. Our methodology explicitly preserves human authority: AI handles mechanical tracking while humans make all creative decisions.

Sony's firmware development incorporates improvements directly informed by our production feedback. Version 3.0 (announced at ISE 2026) includes: optical image stabilisation for long-lens AI tracking, Tracking Range Zone overlays for vertical output monitoring, PTZ Speed Adjustment during auto-framing, and improved interface visibility. This demonstrates an active development cycle between manufacturer and production users.

Scoring is incomplete ⚠ Save Cancel

Criteria	Score
Innovation * How original and forward-thinking is the approach? Whether you built an AI solution, adopted AI within your own events operation, or are bringing an early-stage concept to market, judges want to see genuine originality. Has AI been applied in a new or distinctive way? Does it solve a real problem creatively rather than following the obvious path? Look beyond off-the-shelf deployment and assess the quality of thinking behind the approach.	/ 100
Impact * What difference has this made, or what difference is it credibly expected to make? For live solutions, look for concrete evidence -- engagement rates, time saved, revenue generated, cost reduction, satisfaction scores. For pilot or beta-stage entries, early indicators such as user testing results, pilot outcomes, letters of intent, or projected impact grounded in credible data are all valid. Strong entries will be specific, not vague.	/ 100
Execution * How well has this been implemented or developed? For suppliers and vendors, consider the quality of the build, the robustness of delivery, and how challenges were handled. For organisers, consider how well AI was embedded into operations and how the team managed change. For early-stage entries, assess the quality of the product so far, the clarity of the roadmap, and the credibility of the team's approach. Thoughtful, professional execution at any stage counts highly.	/ 100

Recuse yourself if you have a professional or personal conflict of interest

Scoring is incomplete

Criteria	Score
Results * What has been achieved, and what does the evidence show? For established solutions, consider client outcomes, retention, testimonials, and industry recognition alongside hard metrics. For organisers, attendee feedback, operational improvements, and stakeholder satisfaction all count. For startups or beta entries, judges should look for credible progress -- pilot conversions, early user feedback, investment secured, or strategic partnerships -- and should assess potential alongside proven outcomes. Do not penalise entries for being early stage; reward evidence of meaningful progress and a clear path to impact.	/ 100
